schematic circuit diagram is shown, and a correlation between theoretical and experimentally obtained data is adduced. A block diagram of the power-control system of the reactor is traced. A curve of a transitional process for a total control time of 120 sec is shown, and it is shown that the maximal overcontrol amounts to 208%. By contrast, an analogous transient process in which an ionization chamber is used as a power transducer has a total control time of 19 sec and a maximal overcontrol of 20%. It is apparent that the proposed use of a thermal-transducer computer system is significantly less favorable than a control system with an ionization chamber. However, by using corrective and intensifying (booster) elements, the quality of a transient process can be substantially improved, and, for certain reactor systems which operate on an essentially constant power level, the proposed system is fully practicable. There are 9 figures and 3 references (2 Russian-language Soviet and 1 English-language in Russian translation).

AUTHORS: Susanina, O.G. and Chernozhukov, N.I. 65-10-4/13  
TITLE: An investigation of the Solubility of the Individual Groups of Hydrocarbons of Oil Fractions in Acetone (Issledovaniye rastvorimosti v atsetone otdel'nykh grupp uglevodorodov maslyanykh fraktsiy)  
PERIODICAL: Khimiya i Tekhnologiya Topliva i Masel, 1957, No.10, pp. 14 - 21 (USSR)  
ABSTRACT: The problem of how the individual groups of hydrocarbons in oils can be separated from a polar solvent within a wide range of temperatures was investigated. Two types of raw material were taken for the experiments: a distillate auto oil 10 from a mixture of 10 crude oils from Baku and a distillate of the Surakhansk paraffinic crude. Physico-chemical properties and group composition of the materials are given in Tables 1 and 2, respectively. Acetone was chosen as a solvent and the experiments were carried out in the temperature range - 70 °C to the critical temperature of acetone. The experimental results are given in Tables 3 and 4 and Figs. 1-7. It was established that on decreasing the temperature of acetone solutions of oils, paraffins, naphthenes and aromatic hydrocarbons with a large number of carbon atoms in the side chains crystallise with the formation of saturated solutions in acetone. In respect of the

Card 1/3

65-10-4/13

An Investigation of the Solubility of the Individual Groups of Hydrocarbons of Oil Fractions in Acetone

above groups of hydrocarbons acetone, similarly to non-polar solvents, shows dispersing properties. The main part of aromatic hydrocarbons and resins is strongly retained in acetone solutions even at very low temperatures. It is obvious that these hydrocarbons and resins are combined with the solvent due to the influence of its polar properties. In the temperature range near to the critical temperature of acetone, the precipitation of high molecular hydrocarbons and resins takes place, similarly to their precipitations from propane and other non-polar solvents. The polar properties of acetone appear in a considerable narrowing, in comparison with propane, of the temperature range in which the separation of the second phase (asphalts) takes place. The method of fractional crystallisation of hydrocarbons from solutions of oils in acetone together with chromatographic separation of fractions isolated on silicagel and activated carbon can be used for the analysis of the structure of hydrocarbons in oils. De-paraffinisation of oils at low temperatures in acetone-toluole solutions leads to the separation from the solution of a considerable amount of valuable low solidifying naphthenic and aromatic hydrocarbons. A mixture of 25% of

Card2/3

65-10-4/13

An Investigation of the Solubility of the Individual Groups of Hydrocarbons of Oil Fractions in Acetone

acetone and 75% of toluole separates the above hydrocarbons to the same extent as pure methyl ethylketone. At very low temperatures of de-paraffinisation, a mixture of 25% of methylethylketone and 75% of toluole does not separate valuable hydrocarbons when a high excess (in respect of oil) of solvent is present. There are 7 figures, 4 tables and 2 Russian references.

TITLE: The Solubility of Oil Hydrocarbons in Organic Solvents and Ways of  
the Oil Production Improvement

PERIODICAL: Tr. Mosk. in-t neftekhim. i gaz. prom-sti, 1959, No. 24, pp. 311-340

TEXT: The authors recommend ways of improvement of the lubricant production. Hydrocarbons of higher molecular weight and higher freezing point are in the first place separated at the fractional crystallization of oil hydrocarbons from their solution in acetone. The solubility of the naphthene and paraffin fractions of oils as well as the solubility of a part of the aromatic hydrocarbons and resins result from the effect of the dispersion forces, and the solubility of the remaining part of aromatic hydrocarbons and resins is connected with the action of polar forces. The increase of the dissolving power of the solvent is a consequence of the increase of both its dipole moment and the non-polar portion

The Solubility of Oil Hydrocarbons in Organic Solvents and Ways o<sup>r</sup> the Oil Production Improvement

of its molecule. In both cases, the increase of the dissolving power of the solvent is accompanied with the decrease of its selectivity. There are considered: the mechanism of the de-asphaltizing of a petroleum concentrate by propane; the effects of temperature and quantity of furfurole on the course of refining of the oil distillate of the Tuymazy petroleum; the properties of phenol and furfurole. An increase in the quantity of furfurole in the refining makes up the insufficiency in its dispersion properties; hereat, the quantity of aromatic hydrocarbons being to be eliminated sharply increases, as a result of which the viscosity coefficient of the refined product increases more than at increased refining temperature. By the use of phenol, the output of refined products is lower than for the refining by furfurole in consequence of the higher dissolving power of the former. The high dissolving power of phenol leads to super-refining of oils in consequence of which their resistance to oxidation decreases. By the addition of water to phenol, its dissolving power decreases, and the selection properties and the output of refined products increase, whereat its viscosity coefficient inconsiderably decreases. The treatment of a transformer oil distil-

TITLE: Petroleum refining products as softeners-fillers for butadiene-styrene rubbers

SOURCE: Moscow, Institut neftekhimicheskoy i gazovoy promyshlennosti. Trudy\*, no.  
44, 1963. Neftekhimiya, pererabotka nefti i gaza, 48-57

TOPIC TAGS: petroleum product, plasticizer, filler, butadiene styrene, rubber,  
butadiene styrene rubber filler, butadiene styrene rubber plasticizer, oil refining, oil  
refining product, low temperature resistant rubber, oil filled rubber, rubber  
softener, softener, rubber plasticizer

ABSTRACT: The use of a wide variety of petroleum products as softeners and fillers  
for rubbers was investigated. The physical-chemical properties of the petroleum  
fractions and the compounds separated from them were analyzed. It was found that  
aromatic hydrocarbons combine with rubber better than the paraffin-naphthenic type.  
A change from light to heavy aromatic hydrocarbons causes an increase in the internal  
friction coefficient and the tensile and rupture strength of the rubber, along with a

Card 1/3

L 8766-65

decrease in elasticity and frost resistance. Light aromatic hydrocarbons with a ring number of 1.7-2.0 and an aniline point no higher than 70°C, as well as medium hydrocarbons with a ring number of 2.5-3.0 and an aniline point no higher than 60°C, combine well with and guarantee high vulcanized rubbers. Paraffin-naphthenic hydrocarbons with a ring number of 2.5-3.5 and an aniline point no higher than 125°C also give suitable results. Rubbers containing avtol 18 were compared with those containing other petroleum products. It was noted that rubbers with refined and deparaffined oils having a lower aromatic hydrocarbon content possess a lower brittleness temperature, higher elasticity and significantly lower stability than rubbers with avto 18. However, they are deficient in the sense that they exude oil. The physical-mechanical properties of rubbers containing deasphalted tar oil are comparable to those containing avtol 18. Adding raffinate P to rubbers causes a high stability with large doses and high elasticity at increased temperatures. The use of softeners and fillers is necessary in order to obtain sufficiently high physical-mechanical properties and a high elasticity for rubbers. An example of a softener-tinner is a secondary raffinate obtained by selective refining and removal of paraffin-naphthenate and naphthene-aromatic hydrocarbons. Several methods are proposed for obtaining products of this type; separation by cooling an

Author	: Susanov, Ye. Ya.
Title	: Kinetics of rectification
Periodical	: Neft. khoz., v. 32, #9, 62-69, S 1954
Abstract	: The author attempts to present a theoretical solution of the kinetic problem of the rectification of oil and to work out a basis for computation without empirical correction for efficiency of the process. The theoretical part discusses the true physical concept of the postulate of the "theoretical" stage of the rectification and the efficiency of the real stage. The theory introduced was experimentally confirmed by L. S. Aksel'rod, B. B. Dil'man, I. N. Kuz'minykh and others (Khim. Prom., #1, 2, 1954). Two drawings.

TITLE:	Catalytic reforming of narrow fractions of straight-run gasolines and gas condensates from the Krasnodar region	
PERIODICAL:	Referativnyy zhurnal. Khimiya, no. 18, 1962, 445, abstract 18M133 (Tr. Krashnodarsk. fil. Vses. neftegaz. n.-i. in-ta, no. 8, 1962, 88-95)	
TEXT:	Straight-run gasolines and gas condensates from the Krasnodar region, which contain a large quantity of cyclanes, are a valuable raw material for the production of aromatic hydrocarbons. Catalytic reforming of the narrow fractions ( $60-105^{\circ}\text{C}$ and $105-140^{\circ}\text{C}$ ) separated from these forms of crude was carried out with alumino-platinum catalyst AP-56 (AP-56) in a pilot plant. The flow sheet and description are given. The resulting data show that maximum aromatic hydrocarbon yield is obtained under the following optimum conditions: for the $60-105^{\circ}\text{C}$ fraction,

temperature  $515^{\circ}\text{C}$ , volumetric rate 1, pressure 20 atm.; for the  $105\text{-}140^{\circ}\text{C}$  fraction, temperature  $510^{\circ}\text{C}$ , volumetric rate 1.5, pressure 38 atm. Under rigorous conditions there is considerable formation of aromatic hydrocarbons at the expense of the alkanes. The aromatic yield can be increased 1.2-1.4 times by tightening up process conditions.

TITLE: Blood coagulation and fibrinolytic activity in acute radiation sickness 1965		
SOURCE: AMN SSSR. Vestnik, no. 9, 1965, 70-74		
TOPIC TAGS: radiation sickness, blood, coagulation, hematology		
ABSTRACT: The hemorrhagic syndrome is considered the gravest manifestation of acute radiation sickness and to a great extent determines its degree, duration and outcome. However, despite numerous investigations of the factors responsible for hemorrhage in this disease, the pathogenesis of this phenomenon has not been elucidated. The authors have investigated the functional conditions of coagulation and of the fibrinolytic system of the blood in acute radiation sickness produced by gamma-radiation with Co <sup>60</sup> . 256 "August" strain rats were irradiated with		
UDC: 617-001.28-036.11-07:[616.151.5+616.153. 962.4] Z

	600 rad each. Four phases were discernible during the course of the disease: Phase I--primary reaction (1-2 days following irradiation), II--hidden (3-6 days), III--peak (7-15 days), IV--recovery (20-30 days). Detailed descriptions are presented of the physical appearance and behavior of the animals during the four phases as well as of the changes found in the cellular composition of the blood, bone marrow and spleen. The following changes in the clotting system of the blood were observed following irradiation: initial decrease (phase I) followed by an increase in the coagulation time, reduced tolerance of plasma to heparin, diminished prothrombin activity, increased thrombin time and fibrinogen concentration, first an increase (phase II) then a decrease (Phase III) in thrombin concentration, reduced thermal stability, the emergence of fibrinogen B, reduced fibrinase and increased fibrinolytic activity, diminished platelet count and delayed retraction of the clot. The electron microscope showed disturbances in the fibrin fibers such as rupture and vacuolization. It is evident that the hemorrhagic syndrome appears in the first phase only 24 hours after irradiation as indicated by the presence of blood in the feces at that time. It can therefore be concluded that in acute radiation sickness damage to the blood vessel walls first occurs in the gastrointestinal tract and only later spreads to the vessels of the skin. Also responsible for the hemorrhage	O

TITLE:

On the Relation Between the Shape of the Vapor Isothermal-  
Isobaric Curves and the Distribution of the Components Be-  
tween the Coexisting Phases in Ternary Solution-Ideal Vapor  
Systems (O svyazi mezhdu formoy izoterm-izobar para i.  
raspredeleniyem komponentov mezhdu sosushchestvuyushchimi  
fazami v trekhkomponentnykh sistemakh rastvor-ideal'nyy par)

PERIODICAL:

Zhurnal fizicheskoy khimii, 1958, Vol. 32, Nr 8,  
pp. 1827-1830 (USSR)

ABSTRACT:

Sufficiently accurate data on the composition of coexisting  
liquids and vapors make possible a representation and classi-  
fication of the thermodynamic properties of the system not  
only by changes of the solution but also of the vapor. This  
may be carried out using the differential equation of A.V.  
Stornikin (Ref 1). After modifying the Van der Waals (Van der  
Vaals) equation and after mathematical derivations a formula  
is obtained which after corresponding considerations leads to  
the conclusion that the compositions of the coexisting phases  
are located on a secant of the triangle of concentration. The

On the Relation Between the Shape of the Vapor Isothermal-Isobaric Curves and the Distribution of the Components Between the Coexisting Phases in Ternary Solution-Ideal Vapor Systems.	SOV/76-32-8-16/37	
secant proceeds from that point of the triangle which corresponds to the component with the extreme value of the molecular share. Explanations are given for a triangle diagram of a system with closed isothermal-isobaric curves, with the inner isothermal-isobaric curve corresponding to the vapor surface, and the outer to the surface of the liquid. Finally the author mentions that the problem mentioned was in close relation to the considerations by A.V. Storonkin and M.M. Shul'ts (Ref 3). There are 1 figure and 3 references, all of which are Soviet.

TITLE:	Investigation of the Vapor Pressure of Saturated Solutions of Hydrochloric Aniline in Hydrochloric Acid at 25°C (Issledovaniye davleniya para nasyshchenykh rastvorov solyanokislogo anilina v solyanoy kislote pri 25°C)	
PERIODICAL:	Vestnik Leningradskogo universiteta. Seriya fiziki i khimii, 1959, Nr 1, pp 67-72 (USSR)	
ABSTRACT:	<p>In this paper the authors investigated the solubility and partial pressure of saturated solutions within the system hydrochloric aniline - water-hydrochloric acid. The methods of determination applied were similar to those already described in reference 4. For the solubility of hydrochloric aniline in water the value 52.05 wt% was found (in good agreement with data available in publications), the value 19.74 torr for the steam pressure of water over the saturated solution (value of reference 1; 19.79 torr). All experimental data on the partial pressure and composition of vapor for solutions of <math>C_6H_5N\cdot HCl</math> saturated at 25° in the binary solvent <math>H_2O\text{-}HCl</math> with various percentages of the molar composition of the latter are listed in a table. On the isothermal line of solubility (Fig 1) a maximum of one of both components of the binary</p>	
Card 1/2		

Investigation of the Vapor Pressure of Saturated Solutions of Hydrochloric Aniline in Hydrochloric Acid at 25°C

SOV/54-59-1-8/25

system, i.e., of water was distinctly marked. Further, the authors observed a continuous drop of the partial steam pressure with simultaneous increase of the partial vapor pressure of HCl dependent on the composition of the binary solvent (Fig 2). This agrees with the thermodynamic law since the partial vapor pressures of the components of a binary solvent change always in a monotonous manner and in opposite direction. On the basis of these investigations the authors further dealt with the problem of the mutual positions of the composition of a ternary saturated and binary solution which correspond to turning points of pressure. It was stated herein that the ratio HCl/H<sub>2</sub>O equal to 0.157 of the concentration of the components of the binary solvent corresponds to the pressure minimum in the ternary saturated solution. This value is smaller than that corresponding to a binary azeotropic solution (0.161). There are 3 figures, 1 table, and 9 references, 7 of which are Soviet.

ABSTRACT: Authors examined the practicability of evaluating a ternary system in terms of a binary one by comparing the experimental data with data calculated according to the proposed method and that of Gala (Zhurn. fiz. khimii, v. 33, 1959, pp 24, 35) as well as that of Benjamin et al (Ind. Eng. Chem. 51, 1959, 219). The system benzene-n-hexane-cyclohexane was studied. The experimental and calculated data are summarized in a table which show good agreement with each other. At a constant temperature, the partial pressure of isomeric compounds, which form a close-to-ideal solution, changes in direct proportion to the concentration,

TOPIC TAGS: vapor-liquid system

ABSTRACT: A study of ternary systems in distillation and redistillation processes was directly connected with surface structure of the total vapor pressure (boiling points). Basic factors influencing the shape of the folds of the concentration triangle are: the character of separating action of the third component in relation to the components forming the binary system, in which the fold first is kept; the type of fold (crest or hollow). Corresponding to the factors which determine the direction of shifting of the fold at any point with a temperature change are: ratio of partial molar heat of evaporation on components forming the binary system in which the fold is kept; type of fold. The equation is derived for the equidistribution curve between coexisting phases of 2 components of a ternary solution- the ideal vapor (curve of stability and equality to unit of
